ABSTRACT
To assess and compare different conditioning regimes (laser and conventional) on shear bond strength (SBS) of resin modified glass ionomer cement (RMGIC) bonded to dentinal tissue. Sixty permanent intact human third molars were prepared and allocated into six groups (n=10 each). Group 1, dentin was conditioned with Nd-Yag laser (NYL), Group 2: Er, Cr:YSGG laser (ECL), group 3: total etch adhesive, group 4: self-etch adhesive resin, group 5: 25% polyacrylic acid (PAA) and group 6: no treatment group. After surface conditioning of all fifty samples resin modified glass ionomer cement (RMGIC) was mixed and build up was performed. For SBS testing, specimens (n=10) in each group were placed in a custom jig of a Universal testing machine. For the de-bonded surface fracture analysis was completed using stereomicroscope at 40x magnification. Descriptive statistics i.e., means and standard for SBS were compared using analysis of variance (ANOVA) and Tukey’s post hoc test at a significance level of (p<0.05). The maximum SBS values were observed in PAA (20.44±3.92) and the minimum values were noted (12.54±2.25). RMGIC conditioned with NYL (13.45±2.44) and control group (12.45±2.25) were comparable p>0.05. In laser, irradiated groups admixed failure was common. Dentin conditioned with PAA exhibited cohesive failure. The use of ECL and not NYL has a potential to be used as conditioning regime in clinical setting prior to application of RMGIC.

KEY WORDS: RMGIC, DENTIN CONDITIONING, ER,CR:YSGG, ND-YAG LASER, SHEAR BOND STRENGTH.
Alternative methods in the form of lasers Er,Cr:YSGG (ECL) and Nd:Yag (NYL) to condition tooth surface has displayed convincing results, (Alkhudhairy, AlKheraif, et al., 2018; Alkhudhairy, Naseem, et al., 2018; Vohra et al., 2018, Alkhudhairy, Naseem, Ahmad, et al., 2019; Alkhudhairy, Vohra and Naseem, 2019a; Alkhudhairy, Vohra, Naseem, et al., 2019). Interestingly, existing data suggests that lased dentinal surface exhibit open tubules, increase roughness and caters resembling to acid etched surface, ( Ekworapoj et al., 2007, Alkhudhairy, Vohra and Naseem, 2019a). Moreover, it provides a clean surface free of smear layer and enhances tooth adhesion (Kobayashi et al., 2003). To our knowledge from indexed literature limited evidence on the use of lasers (ECL, NYL) as dentin conditioner prior to GIC application exists. Moreover, efficacy of different conditioning regimes and their comparison with laser conditioning is scarce and limited. It is hypothesized that dentin conditioned with ECL and NYL will exhibit bond strength similar to dentin treated with other surface regimens. Therefore, the aim of the present study was to assess and compare different conditioning regimes (lased and conventional) on shear bond strength (SBS) of RMGIC bonded to dentinal tissue.

MATERIAL AND METHODS

Sixty permanent intact human third molars free of caries, cracks were used as a bonding substrate. Teeth were isolated and stored in 0.5% chloramine T solution at 4 °C for duration of one month to disinfect, following storage in distilled water until use. With a low speed diamond saw (Isomet, Buehler, USA) the enamel surface was removed, and dentin surface was made flat. To attain a homogenize surface roughness, dentin polishing using silicon carbide grinding discs 800 and 1200 grits (Buehler, Great Britain UK) under water irrigation on a polishing machine (Stone Liu Shanghai Smedent Medical Instrument Co., Ltd) was used. Teeth were mounted vertically in acrylic resin within the sections of polyvinyl pipes (6mm diameter) up to cement-o-enamel junction (CEJ). Now based on the conditioning protocol the samples were allocated into six groups (n=10 each).

Group 1: Dentin surface was conditioned with Nd-Yag laser (NYL) (Hoya ConBio Delight, Sweden &t Martina, Padova, Italy) at 150 mJ, 10 Hz and 1W for a duration of 60 sec in a non-contact circular motion using a quartz optical fibre having diameter of 320-μm.

Group 2: The surface of bonded dentin samples were treated with Er,Cr:YSGG laser (ECL) (Biolase- Waterlase I-Plus) at 0.5W and power 30Hz in a circular, non-contact position using tip MZ6 from a distance of 1mm for duration of 60 sec.

Group 3: 37% phosphoric acid was applied on dentin for 5 sec and washed with water spray thoroughly for 10sec. Bonding agent was applied and air dried for 10sec without the surface being desiccated. The bonding agent was reapplied and photo cured (Bluephase G2, Ivoclar, Vivadent) for 10 sec.

Group 4: On bonded dentinal surface self-etching primer was implemented and left undisturbed for 20 sec, gently air dried. Bonding agent was applied, spread uniformly with a light air stream, and light cured (Bluephase G2, Ivoclar, Vivadent) for 10 s.

Group 5: Polyacrylic acid (PAA) was applied on bonded dentinal surface and was left undisturbed for 10 sec. The surface was rinsed for 10 sec and air dried 5 sec without desiccation.

Group 6: Dentinal surface of this group did not receive any surface treatment.

After surface conditioning regimes of all fifty samples resin modified glass ionomer cement (RMGIC) Fuji II LC GC, Tokyo, Japan was mixed according to manufacturer instructions and build up was done incrementally using a tofelmire matrix holder at a height of 5mm and cured 20sec (Bluephase G2, Ivoclar, Vivadent). The specimens were covered with GC varnish (GC, America, Inc) and stored in distilled water at 24°C until use. Shear bond Strength (SBS) : For SBS testing specimen (n=10) each group were placed in a custom jig of a Universal testing machine (Lloyd’s, LF, plus, Ametek Inc, Great Britain, UK) under a cross head speed of 1mm/ min until failure occurred. The force was applied parallel to bonded samples. The maximum force required to generate fracture was recorded in MPa.

Failure mode Analysis: Fracture analysis was completed by two examiners using stereomicroscope at 40x magnification (Preconfigured Olympus Stereo Microscope Systems, SZX7, Edmund Optics UK). Type of failure was categorized into adhesive cohesive and admixed.

Statistical Analysis: SBS data was tabulated using statistical program for social science (SPSS version 19, Inc., Chicago, US). Normality of data obtained was assessed using Kolmogorov-Smirnov test. Descriptive statistics i.e., means and standard for SBS were compared using analysis of variance (ANOVA) and Tukey’s post hoc test at a significance level of (p < 0.05)

RESULTS AND DISCUSSION

The data observed in the existing study was normally distributed. Table 1 displays SBS of RMGIC bonded to different conditioning regimes to dentin. The maximum SBS values were observed in PAA (20.44±3.92) and the minimum values were noted (12.54±2.25). RMGIC conditioned with NYL (13.45±2.44) and control group (12.45±2.25) were comparable p>0.05. Furthermore, conditioning of RMGIC with ECL (18.54±3.24), TE (19.44±3.74), SE (18.22±3.55) and PAA (20.44±3.92) were comparable p>0.05. Mode of failure amongst all experimental groups, adhesive failure type was pertinent (Figure 1). In laser, irradiated groups admixed failure was common. Moreover, In TE and SE groups adhesive failure was found in majority. Dentin conditioned with PAA exhibited cohesive failure. The existing study was based on the hypothesis that dentin conditioned with ECL and NYL and bonded to RMGIC will exhibit comparable bond
integrity to different conditioning regimes. The present in-vitro experiment revealed that bond strength of dentin conditioned with ECL was comparable to PAA, SE and TE. Whereas, dentin conditioned with NYL displayed low bond strength scores compared to different conditioning regimes but was comparable to non-treatment group. Therefore, the hypothesis was partially accepted. The durability of a restoration is contingent on the adhesive capability, which can be assessed by SBS testing. In the present study SBS of the restoration was determined using universal testing machine. The method is simple to use, widely acceptable, provides comparative analysis and samples does not require further processing after bonding procedures (Sirisha, Rambabu, Ravishankar, et al., 2014; Sirisha, Rambabu, Shankar, et al., 2014).

Conditioners are used to promote adhesion, remove smear layer, improve surface energy and promote surface wettability (Tanumiharja et al., 2000). In the present study ECL at 0.5 W and 30 Hz was used to condition dentin prior to RMGIC. ECL works at a wavelength of 2780 micrometres displays strong affinity to hydroxyapatite crystals in dentin and water. In the existing study ECL at low level exhibited SBS (18.54±3.24) similar to dentin conditioned with PAA (20.44±3.92). This finding was in line with a study by (Alkhudhairy, Al-Johany, Naseem, et al., 2019; Ekworapoj et al., 2007; Garbui et al., 2013). A probable explanation to these conclusions is ECL at low level causes loss of water and collapse of the dentinal collagen resulting in reduction of hydrophilicity of dentin, which indirectly improves the suitability of hydrophobic polymeric materials like RMGIC to adhere well with the dentin structure (Alkhudhairy, Al-Johany, Naseem, et al., 2019). Furthermore, lased dentin results in smear free layer following easy penetration of RMGIC exhibiting strong bond affinity (Ekworapoj et al., 2007). Moreover, due to improved surface energy of lased dentin ionic exchange between the intermediary layer of RMGIC and dentin structure might influence better bond integrity (Alkhudhairy, Vohra and Naseem, 2019b).

The other laser used in the present study NYL (13.45±2.44) exhibited statistically significant difference compared to PAA (20.44±3.92) TE (19.44±3.74) and SE (18.22±3.55) experimental groups. These findings were not in harmony with the outcome of work carried out by Kobayashi et al., (2003) and Aljdaimi et al., (2018).

Our findings, of the present study were in concurrent with the results of (Besnault et al., 2004; Coutinho et al., 2006). Multiple explanations can be given for such outcomes. Primary, reason is SE adhesives and RMGIC both have carbon-carbon bonds which on polymerization changes to covalent bonds improving adhesion. Secondly, presence of water in both RMGIC and SE adhesives enhances their wettability on dentinal surface which indirectly improve RMGIC spread over dentin conditioned surfaces with SE adhesives. Thirdly, low modulus of elasticity of RMGIC renders low polymerization shrinkage compared to resin composites (Besnault et al., 2004; Coutinho et al., 2006). Based on the result of our finding the author recommends use of SE adhesives to condition dentin as the conditioning method is less technique sensitive and more user friendly and provide desirable results similar to TE.

The highest bond strength scores were observed in group conditioned with PAA (20.44±3.92). Possible explanation reported for this outcome is that dentinal surface conditioned with acid creates irregularities and pores on the substrate surface boosting adhesion (Hamama et al., 2014). This finding was in synchronization with work of Tanumiharja et al., (2000). Moreover, in the same study by Tanumiharja et al.,(2000) reported that

wettability of surface enhances infiltration of HEMA into collagen network of dentin increasing bond scores. Recently, work by Sauro et al., (2018) reported dentin conditioned with PAA increases the risk of collagen collapse and degradation at dentin/ material interface under prolong stress, mechanical cycling and saliva immersion ultimately leading to bond failure. Therefore, though the SBS values of PAA conditioned group is the highest in the existing study, PAA as conditioner should be used with caution. Based on fracture analysis, admixed and cohesive failure was found to be pertinent in lased dentin and surface conditioned with PAA. Such failure type can be attributed to porosity within the material which act as a centre of stress resulting in breakage within the material, implying better bond integrity (Saraç et al., 2009).

The biggest limitation of the study was not carrying out the micro morphological analysis of the bonded surface. Conditioning of dentin surface using laser is a unique concept and needs further clinical and non-clinical assessment in the form of durability testing of conditioned surface, surface energy measurements, surface profiling and scanning electron microscopic evaluation. Promising invitro results not always can assure clinical success. These laboratory-based studies act as a screening tool for selection of materials used in in-vivo study design. Therefore, more studies to extrapolate the findings and recommendations of present study should be performed.

CONCLUSION

The use of ECL and not NYL has a protentional to be used as conditioning regime in clinical setting prior to application of RMGIC.
