

Evaluation of industrial effluent and domestic sewage genotoxicity using *Allium cepa* bioassay

Rajesh Paul and Jashodeb Arjun*

Zoology Department Lumbding College, Lumbding, 782447, Assam

ABSTRACT

Living organisms including both plants and animals being exposed to polluted water bodies can be impacted. In current investigation the genotoxic effect of industrial effluent and domestic sewage of Barak valley region, Assam, India was investigated using both morphological and root chromosome assay on *Allium cepa*. The mean root lengths of onions exposed to different concentrations of the effluent and sewage (10%, 25% and 50%) were measured for 3 consecutive days for 24, 48 and 72 hrs and the results were compared. The mean root length was statistically evaluated by the analysis of variance. There was both significant increase and decrease in root length among the exposed onion bulbs. Total aberrations increased significantly as concentration increased ($p < 0.05$). Both effluent and sewage samples were recorded to cause harmful damages in the exposed onion test samples. These results demonstrated that the *Allium* test is a useful screening test for the evaluation of toxicity caused by sewage and effluent samples not only at the morphological level but also at the cytogenetic level; and hence pollution in water bodies is a major cause of concern. Thus, sincere measures should be undertaken regarding the direct disposal of industrial effluents and domestic sewage and protection of water bodies including its flora and fauna.

KEY WORDS: PAPER MILL EFFLUENTS, DOMESTIC SEWAGE, *ALLIUM CEPA* TEST

INTRODUCTION

Over two third of Earth's surface is covered by water; less than a third is taken up by land. As Earth's population continues to grow, people are putting ever-increasing pressure on the planet's water resources. In a sense, our oceans, rivers and other inland waters are being squeezed by human activities, not so that they take up less room, but so their quality is reduced. Poorer water quality leads to pollution in water bodies. Water pollution nowadays is a major global problem. It requires ongoing evaluation and revision of water resource policy at all levels. It has been recorded that water pollution is the leading worldwide cause of death and diseases and it accounts for the death of more than 14,000 people daily. India and China are the two countries with high levels of water pollution: An estimated 580 people in India die of water pollution related illness including water borne diseases. Water pollution results in contamination of water bodies like rivers, lakes, aquifer, etc. due to human activities, (Bennet, 1997, Prasad and Rao, 2010. Bakare et al, 2017, Anacleto et al, 2017).

Pollution in water bodies occurs when contaminants gets introduced into the natural environment. For example, releasing inadequately treated waste water into natural water bodies leading to degradation of aquatic ecosystem. This in turn can cause public health problems for people living in downstream as people are using this polluted water for regular domestic activities like bathing, washing, drinking, irrigation, etc. Researches have revealed that the sources of water pollution may be point sources and non-point sources. Point sources have an identifiable cause as storm drain, waste water treatment plant or streams. Non-point sources are more diffuse like agricultural runoff, (Zaiad, 2010). With the increasing development of industrial resources the risk of water pollution has also increased. Not only the industrial resources but also the inadequate system of dumping of municipal sewage has resulted in pollution of water bodies and its aquatic ecosystem including both aquatic flora and fauna.

Researches till date have revealed that dissolved contaminants in both effluents and sewages when exposed to water bodies not only harms plant growth but also forces plants to absorb dangerous chemicals and pollutants which gets passed to animals and human through consumption and other modes (Sik *et al*, 2009). In a work done on the variable actions of *Allium sepa* and its usage as a bio indicator of cadmium toxicity, plants were exposed to increasing concentrations of cadmium, where cadmium was observed to cause inhibition of root and leaves growth and elongation which serve as a tool for characterizing the bio indication of cadmium exposure in waste and effluent condition, (Bakare et al, 2017).

The direct application of industrial sludges were recorded to harm the local biota in an investigation where the genotoxicity of industrial sludges was assessed using various plant including *A. cepa* where *A. cepa* test was found to be effective in detection of damages (Anacleto et al, 2017).

Studies about phytotoxic effects of waste waters and effluents started in 1970s where researches were conducted taking sugar cane, eucalyptus, *Triticum aestivum*, *Brassica campastris*, Sorghum, rice, and many more. *Allium cepa* is the largest genus of petaloid monocotyledons, containing hundreds of species naturally distributed in temperate climates of the northern hemisphere (Koçyiğit & Özhatay, 2010). This test has important advantages (Zegura, 2009) and has been used from many years in investigating physical and chemical mutagenesis and cytogenetic effects in mitotic cell division. *Allium cepa* is important since it is an excellent model in-vivo, where the roots grow in direct contact with the substance of interest enabling possible damage to the DNA of eukaryotes to be predicted. It is advantageous to use the *Allium cepa* test system since its main component is a vascular plant, making it an evaluating environmental pollutant, detecting mutagens (Gupta et al, 2009).

The present investigation was designed to examine the level of morphological and genotoxic damages caused by industrial effluents as well as domestic sewages on *Allium cepa* so that proper safety measures can be taken not only for the protection of water quality but also preventive measures can be taken against the damages caused to aquatic ecosystem prior to exposure of effluents and sewage.

MATERIALS AND METHODS

For present investigation raw paper mill effluent sample was collected from the outlet pipes in the local river Barak of the valley. The domestic sewage which was selected for comparative analysis was collected from Silchar, Municipal drainage system at Tarapur area, where all the debris and discharges of the whole locality have been found to be discharged. Both effluent and sewage samples were collected in plastic gallons, pH was measured and stored at -20°C to prevent further microbial growth.

The common purple onion, *Allium cepa* (2n=16) bulbs (1.5–2.0 cm diameter) used for this study was procured from organic farmers of almost equal weight age. The dried out scales were carefully removed leaving the ring of the root primordial intact (Fiskesjo, 2011). Then they were kept in moist condition to let root grow for three days, this help select onion with synchronous growth. For each test, 10 *A. cepa* bulbs purchased from organic farmers were set up to produce roots in filtered and dechlorinated tap water for three days and then

transferred to the test solutions. Tap water was previously filtered in a bio-activated coal filter to remove chlorine and its by-products commonly used for disinfecting drinking water. Three litres of water were aerated over a period of 24 h before filling the test tubes. For positive control mitomycin C was selected. Mitomycins are a family of azinidines containing natural products isolated from *Streptomyces lavendulae*. Mitomycin C is a potent DNA crosslinker. A single cross link per genome has shown to be effective in killing bacteria. This is accomplished by reductive activities followed by 2 N -Alkylation. Both alkylation are sequence specific for a guanine nucleotide sequence.

Three different concentrations of both the effluents and sewage were selected as 10%, 25% and 50% for exposure through prior standardization. During the *Allium cepa* assay, all selected onions were exposed to the selected concentrations of effluent and sewage for 24hrs, 48hrs and 72 hrs, respectively. The growth in roots were recorded till the third day of exposure in water and after that the variation in root growth were recorded after every 24 hrs for next three consecutive days till 72hrs and the data were recorded and compared. For mitotic studies, growth inhibition tests were carried out for each sample, to find its toxicity level. After every 24hrs of exposure, 3 to 4 healthy root tips from each bulb were prepared for the microscopic slides.

The emerged root tips of the onion bulbs in the different concentration of sewage and effluent were fixed and macerated in a solution of 45% acetic acid (9 parts) and 1 N HCl (1 part) at 50 °C for 10 min, followed by squashing in 2% Acetocarmine stain for 15 minutes. The modified conventional Feulgen-squash method (Sharma and Dphil, 2012) was used to prepare permanent slides of root meristems. The root tips were put in 1 normal hydrochloric acid for five minutes to soften the tissue. The macerated and stained root tips were covered with cover slip and squashed. Minimum 3-4 Slides were prepared per bulb for microscopic observation. Approximately three thousand cells were examined per onion to remove the errors and classified according to the chromosomal aberrations presented including bridges, fragments and chromosome lagging.

Results were presented as Mean±SE where mean value was calculated from three individual readings of a particular set. ANOVA was performed to determine the level of significance from the set of onion bulbs. ANOVA was done using graph pad PRISM (Graph pad Inc., san Diego, CA, USA).

RESULTS AND DISCUSSION

Water pollution can be caused by a number of sources ranging from industrial resources and sewage treatment

plants and factories to mining activities, paved roads and agricultural runoff. Such issues have become one of the biggest problems in many developing and developed countries. These pollutants when not treated properly, can cause mutagenic or toxic effects directly on humans, affecting human health, resulting in diseases like cancer, congenital malformations, and cardiovascular diseases (Grover & Kauer, 2009). Siddiqui and his group (Siddiqui et al., 2011) have worked to validate plant-based tests for assessing the toxicity of water in India.

The *Allium* test is advantageous as genotoxicity screening assay, as *Allium* root cells possess the mixed function oxidase system which is capable of activating promutagens or genotoxic chemicals (Odeigah et al; 1997a). In the *Allium* test, inhibition of rooting and the appearance of stunted roots indicate retardation of growth and genotoxicity, while root wilting explains toxicity (Odeigah et al; 1997b). Both growth retardation and root wilting are accompanied by suppression of mitotic activity and remarkable chromosomal aberration. The present findings provide evidence that effluent and sewage inhibited root growth and caused growth retardation. The reason behind growth inhibition may be due to high rate of chemical oxygen demand which affected certain physiological processes leading to the disturbance in the balance between promoter and inhibitors of endogenous growth regulator (Gill and Saggoo, 2010).

Growth inhibition was most recorded at 50% concentration along with a marked decrease in root length when compared with the control. This is usually accompanied by an increase in chromosome aberrations (Amin and Muzahid, 2009). The suppression of mitotic activity was often used in tracing cytotoxicity (Smaka-Kinel et al., 2013). In our study a decrease in the mitotic index was found as the concentration of effluent increased which indicates the cytotoxic effect of sewage and industrial effluent. Chromosomal aberrations were observed to increase as the concentration of effluent and sewage increased. Among the chromosomal aberrations observed, IN, EN and CF were most frequent in all concentrations and kept on increasing from concentrations of industrial effluent towards higher concentrations of sewage. Such findings are responsible for the completely decayed roots found in 25% and 50% concentration. The most common abnormalities were c-mitosis and disturbed metaphase. Sticky chromosomes and binucleated cells were recorded in noticeable amount. In addition to the above, at anaphase and telophase bridges, lagging chromosomes and irregular anaphase were also observed. The mitotic index in the root meristems grown in the negative control ranged from 17.3 to 19.8.

Table 2 shows the mitotic index values in root meristems growth in different concentrations of effluent
